What is JEWEL?

JEWEL is a Monte Carlo High Energy generator whose name stands for Jet Evolution with Energy Loss. It propagates partons inside a thermal medium that simulates heavy-ion collisions in accelerators such as RHIC or LHC.

What is JEWEL?

JEWEL is a Monte Carlo High Energy generator whose name stands for Jet Evolution with Energy Loss. It propagates partons inside a thermal medium that simulates heavy-ion collisions in accelerators such as RHIC or LHC.

It accomplishes this by use of a perturbative approach, combining regular parton shower with successive scatterings:

Event Generations

The process of event generation is described by the following:

Event Generations

The process of event generation is described by the following:

- First, PYTHIA is called to calculate the initial scatterings of the partons inside the nuclei;

Event Generations

The process of event generation is described by the following:

- First, PYTHIA is called to calculate the initial scatterings of the partons inside the nuclei;
- The scattered partons are then propagated through the medium with JEWEL, where the medium is seen by the parton as a collection of scattering centres;

Event Generations

The process of event generation is described by the following:

- First, PYTHIA is called to calculate the initial scatterings of the partons inside the nuclei;
- The scattered partons are then propagated through the medium with JEWEL, where the medium is seen by the parton as a collection of scattering centres;
- Once all of the partons have reached the minimum of virtuality, given by an infrared regulator, they are given back to PYTHIA for hadronization;

Physics of JEWEL

The use of perturbative approach is dealt with by making use of a probabilistic interpretation of the Sudakov form factor:

$$S_a(t_h, t_c) = \exp \left\{ - \int_{t_c}^{t_h} \frac{dt}{t} \int_{z_{min}}^{z_{max}} dz \sum_b \frac{\alpha(k_{\perp}^2)}{2\pi} \hat{P}_{ab}(z) \right\} \quad (1)$$

The use of perturbative approach is dealt with by making use of a probabilistic interpretation of the Sudakov form factor:

$$S_a(t_h, t_c) = \exp \left\{ - \int_{t_c}^{t_h} \frac{dt}{t} \int_{z_{min}}^{z_{max}} dz \sum_b \frac{\alpha(k_{\perp}^2)}{2\pi} \hat{P}_{ab}(z) \right\} \quad (1)$$

Which means we can take it as the probability that a parton a emits no resolvable radiation between the scales t_c and t_h .

Physics of JEWEL

The Sudakov form factor is used to perform the evolution by enforcing radiation until the parton reaches the t_c *cut-off*.

Physics of JEWEL

The Sudakov form factor is used to perform the evolution by enforcing radiation until the parton reaches the t_c *cut-off*.

Besides that, the medium, seen as a collection of scattering centers by the parton, also has the probability of interaction.

Physics of JEWEL

The Sudakov form factor is used to perform the evolution by enforcing radiation until the parton reaches the t_c *cut-off*.

Besides that, the medium, seen as a collection of scattering centers by the parton, also has the probability of interaction.

This probability is given by the regular cross-section of a $2 \rightarrow 2$ process, given by:

$$\sigma_i(E, T) = \int_0^{|\hat{t}|_{\max}(E, T)} d|\hat{t}| \int_{x_{\min}(|\hat{t}|)}^{x_{\max}(|\hat{t}|)} dx \sum_{j \in \{q, \bar{q}, g\}} f_j^i(x, \hat{t}) \frac{d\sigma}{d\hat{t}}(x\hat{s}, |\hat{t}|) \quad (2)$$

What to do with JEWEL?

Initial Conditions

The model employed by JEWEL is a variant of Bjorken model that approaches the initial conditions by the definition of the nuclear thickness function:

$$T(x, y) = \int dz \rho(x, y, z) \quad (3)$$

Initial Conditions

The nuclear thickness functions are then used to define a reduced thickness by:

$$n(b, x, y) = T_A(x - \frac{b}{2}, y) \left(1 - \exp \left(\sigma_{NN} T_B(x + \frac{b}{2}, y) \right) \right) + T_B(x + \frac{b}{2}, y) \left(1 - \exp \left(\sigma_{NN} T_A(x - \frac{b}{2}, y) \right) \right) \quad (4)$$

Where σ_{NN} is the nuclear cross-section and b is the impact parameter.

Initial Conditions

This reduced thickness is then applied to take a map of the initial energy density:

$$\epsilon(x, y, b, \tau_i) = \epsilon_i \frac{n_{part}(x, y, b)}{\langle n_{part} \rangle (b=0)} \quad (5)$$

Where $\langle n_{part} \rangle (b=0) \approx \frac{2A}{\pi R_A}$.

Initial Conditions

The value of ϵ_i is determined by an initial temperature given as a parameter to JEWEL. This translation is made through the use of the relation $\epsilon_i \propto T_i^4$.

What to do with JEWEL?

Medium Evolution

The medium evolution is performed analytically by use of:

$$\epsilon(x, y, b, \tau) = \epsilon_i(x, y, b, \tau_i) \left(\frac{\tau}{\tau_i} \right)^{-\frac{4}{3}} \quad (6)$$

Medium Evolution

The medium evolution is performed analytically by use of:

$$\epsilon(x, y, b, \tau) = \epsilon_i(x, y, b, \tau_i) \left(\frac{\tau}{\tau_i} \right)^{-\frac{4}{3}} \quad (6)$$

This that the temperature evolves according to:

$$T(x, y, b, \tau) \propto \epsilon(x, y, b, \tau_i)^{1/4} \left(\frac{\tau}{\tau_i} \right)^{-\frac{4}{3}} \quad (7)$$

Jet Algorithms

Today, the main type of algorithm to cluster particles from a given event into jets, thus defining a jet, are the sequential recombination algorithms. They define a distance functions between particles:

Jet Algorithms

Today, the main type of algorithm to cluster particles from a given event into jets, thus defining a jet, are the sequential recombination algorithms. They define a distance functions between particles:

$$d_{ij} = \min(p_{ti}^{2p}, p_{tj}^{2p}) \frac{\Delta R_{ij}^2}{R^2} \quad (8)$$

Jet Algorithms

Today, the main type of algorithm to cluster particles from a given event into jets, thus defining a jet, are the sequential recombination algorithms. They define a distance functions between particles:

$$d_{ij} = \min(p_{ti}^{2p}, p_{tj}^{2p}) \frac{\Delta R_{ij}^2}{R^2} \quad (8)$$

Then a process of iteration is realized, where the particles with minimum d_{ij} are combined to form the given jets.

Jet Algorithms

Once the jets are found, one class of the possible observables are the jet shape observables.

Jet Algorithms

Once the jets are found, one class of the possible observables are the jet shape observables.

These reflect much of the evolution that occurs in the jet formation, as well as the process of hadronization.

What to do with JEWEL?

SoftDrop Procedure

One form of extracting information about jet shape is through the SoftDrop Procedure.

SoftDrop Procedure

One form of extracting information about jet shape is through the SoftDrop Procedure.

This is done by undoing the last step of the jet recombination.

SoftDrop Procedure

One form of extracting information about jet shape is through the SoftDrop Procedure.

This is done by undoing the last step of the jet recombination.

The SoftDrop condition is:

$$\frac{\min(p_{T1}, p_{T2})}{p_{T1} + p_{T2}} > z_{cut} \left(\frac{\Delta R_{12}}{R_0} \right)^\beta \quad (9)$$

SoftDrop Procedure

Once the condition has been applied, the quantity:

$$\frac{\min(p_{T1}, p_{T2})}{p_{T1} + p_{T2}} \quad (10)$$

Reflects an observable that is usually related to the first splitting of the parent parton.

SoftDrop Procedure

Once the condition has been applied, the quantity:

$$\frac{\min(p_{T1}, p_{T2})}{p_{T1} + p_{T2}} \quad (10)$$

Reflects an observable that is usually related to the first splitting of the parent parton.

This can be seen in the results of the fact that they follow the Altarelli-Parisi splitting functions.

What to do with JEWEL?

JEWEL Validation

The validation of JEWEL has been performed by comparing with experiments such as:

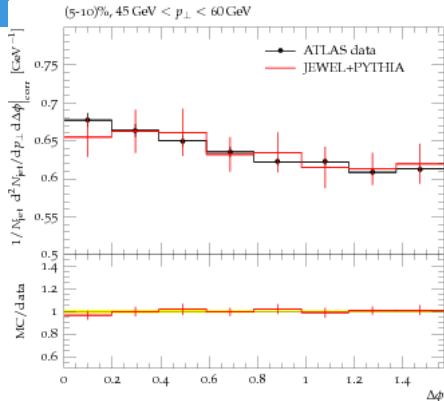

Centrality dependence of the angular distribution of single inclusive jets in Pb+Pb collisions at $\sqrt{s_{NN}} = 2.76 \text{ TeV}$ for a jet radius $R = 0.2$ and $|\eta_{\text{jet}}| < 2.1$ in the range $45 \text{ GeV} < p_t < 60 \text{ GeV}$.
